Chapter I

A Weak Post's Theorem and the Deduction Theorem Retold

This note retells

- (1) A weak form of Post's theorem: If $\underline{\Gamma}$ is finite and $\Gamma \models_{\text{taut}} A$, then $\Gamma \vdash A$ and derives as a corollary the Deduction Theorem:
- (2) If $\Gamma, A \vdash B$, then $\Gamma \vdash A \to B$.

1. Some tools

We will employ below the following Lemma.

1.1 Lemma.
$$\neg A \lor C, \neg B \lor C \vdash \neg (A \lor B) \lor C$$
.

Proof. Here $\Gamma = {\neg A \lor C, \neg B \lor C}$.

$$\neg (A \lor B) \lor C$$

$$\Leftrightarrow \left\langle \text{Leib: } r \lor C + \text{deMorgan} \right\rangle$$

$$(\neg A \land \neg B) \lor C$$

$$\Leftrightarrow \left\langle \text{distrib. of } \lor \text{ over } \land \right\rangle$$

$$(\neg A \lor C) \land (\neg B \lor C) \quad \text{bingo by "join"!} \quad \Box$$

- **1.2 Corollary.** $\vdash \neg (A \lor B) \lor C \equiv (\neg A \lor C) \land (\neg B \lor C).$
- **1.3 Main Lemma.** Suppose that A contains none of the symbols $\top, \bot, \rightarrow, \land, \equiv$. If $\models_{taut} A$, then $\vdash A$.

Proof. Under the assumption, A is an \vee -chain, that is, it has the form

$$A_1 \lor A_2 \lor A_3 \lor \ldots \lor A_i \lor \ldots \lor A_n \tag{1}$$

where none of the A_i has the form $B \vee C$.

In (1) we assume without loss of generality that n > 1, due to the axiom $X \vee X \equiv X$ —that is, in the contrary case we can use $A \vee A$ instead, which is a tautology as well. Moreover, (1), that is A, is written in <u>least parenthesised</u> notation.

Let us call an A_i reducible iff it has the form $\neg(C \lor D)$ or $\neg(\neg C)$. Otherwise it is *irreducible*. Thus, the only possible irreducible A_i have the form p or $\neg p$ (where p is a variable). We say that p "occurs positively in ... $\lor p \lor ...$ ", while it "occurs negatively in ... $\lor \neg p \lor ...$ ". In, for example, $p \lor \neg p$ it occurs both positively and negatively.

By definition we will say that A is irreducible iff all the A_i are.

We define the reducibility degree, of A_i —in symbols, $rd(A_i)$ — to be the number of \neg or \lor connectives in it, not counting a possible leading \neg .

The reducibility degree of A is the sum of the reducibility degrees of all its A_i .

By induction on rd(A) we now prove the main lemma, on the stated hypothesis that $\models_{taut} A$.

For the basis, let A be an irreducible tautology (rd(A) = 0). It must be that A is a string of the form "···· $\lor p \lor \cdots \neg p \lor \cdots$ " for some p, otherwise, if no p appears both "positively" and "negatively", then we can find a truth-assignment that makes A false (\mathbf{f}) —a contradiction to its tautologyhood. To see that we can do this, just assign \mathbf{f} to p's that occur **positively only**, and \mathbf{t} to those that occur **negatively only**.

Now

$$A \\ \Leftrightarrow \left\langle \text{commuting terms of an } \vee \text{-chain} \right\rangle \\ p \vee \neg p \vee B \quad \text{(what is "B"?)} \\ \Leftrightarrow \left\langle \text{Leib: } r \vee B + \text{excluded middle, plus Red.} \top \text{ thm.} \right\rangle \\ \top \vee B \quad \text{bingo!}$$

Thus $\vdash A$ which settles the *Basis*-case rd(A) = 0.

We now argue the case where rd(A) = n + 1, on the I.H. that for any formula Q—restricted as in the lemma statement— with $rd(Q) \leq n$, we have that $\models_{taut} Q$ implies $\vdash Q$.

By commutativity (symmetry) of " \vee ", let us assume without restricting generality that $rd(A_1) > 0$.

We have two cases:

1. Some tools 3

(1) A_1 is the string $\neg \neg C$, hence A has the form $\neg \neg C \lor D$. Clearly $\models_{taut} C \lor D$. Moreover, $rd(C \lor D) < rd(\neg \neg C \lor D)$, hence

$$\vdash C \lor D$$

by the I.H. But,

$$\neg \neg C \lor D$$

$$\Leftrightarrow \Big\langle \text{Leib: } r \lor D + \vdash \neg \neg X \equiv X \Big\rangle$$

$$C \lor D \quad \text{bingo!}$$

Hence, $\vdash \neg \neg C \lor D$, that is, $\vdash A$ in this case.

One more case to go:

(2) A_1 is the string $\neg (C \lor D)$, hence A has the form $\neg (C \lor D) \lor E$.

We want:
$$\vdash \neg (C \lor D) \lor E$$
 (i)

By 1.2 and from $\models_{taut} \neg (C \lor D) \lor E$ —this says $\models_{taut} A$ — we immediately get that

$$\models_{taut} \neg C \lor E$$
 (ii)

and

$$\models_{taut} \neg D \lor E$$
 (iii)

from the \equiv and \wedge truth tables.

Since the rd of each of (ii) and (iii) is smaller than that of A, by I.H. we obtain

$$\vdash \neg C \lor E$$

and

$$\vdash \neg D \lor E$$

which by 1.1 yield the validity of (i).

We are done, **except for one small detail:** If we had changed an "original" A into $A \vee A$, then we have proved $\vdash A \vee A$. The idempotent axiom and Eqn then yield $\vdash A$.

We are now removing the restriction on ${\cal A}$ regarding its connectives and costants:

1.4 Metatheorem. (Post's Theorem) $If \models_{taut} A, then \vdash A.$

Proof. First, we note the following equivalences. The ones to the left of "also" follow from the ones to the right by <u>soundness</u>. The ones to the right are known from class (or follow trivially thereoff): The first is the Excluded Middle

Axiom augmented by "Redundant \top ". The one below it follows from simple manipulation and $\vdash \bot \equiv \neg \top$. All the others have been explicitly covered.

$$\models_{taut} \top \equiv \neg p \lor p, \text{ also } \vdash \top \equiv \neg p \lor p$$

$$\models_{taut} \bot \equiv \neg (\neg p \lor p), \text{ also } \vdash \bot \equiv \neg (\neg p \lor p)$$

$$\models_{taut} C \to D \equiv \neg C \lor D, \text{ also } \vdash C \to D \equiv \neg C \lor D$$

$$\models_{taut} C \land D \equiv \neg (\neg C \lor \neg D), \text{ also } \vdash C \land D \equiv \neg (\neg C \lor \neg D)$$

$$\models_{taut} (C \equiv D) \equiv ((C \to D) \land (D \to C)), \text{ also } \vdash (C \equiv D) \equiv ((C \to D) \land (D \to C))$$
(I.1)

Using the I.1 above, we eliminate, in order, all the \equiv , then all the \wedge , then all the \rightarrow and finally all the \perp and all the \top . Let us assume that our process eliminates **one** unwanted symbol at a time.

Thus, starting from A we will generate a sequence of formulae

$$F_1, F_2, F_3, \ldots, F_n$$

where F_n contains no $\top, \bot, \land, \rightarrow, \equiv$.

I am using here F_1 is an alias for A. We will also give to F_n an alias A'. Now in view of the *provable equivalences* of I.1 (**right column**), each transformation step is the result of a Leib application, thus we have

$$A \Leftrightarrow \left\langle \text{Leib from I.1} \right\rangle$$

$$F_{2} \Leftrightarrow \left\langle \text{Leib from I.1} \right\rangle$$

$$F_{3} \Leftrightarrow \left\langle \text{Leib from I.1} \right\rangle$$

$$F_{4} \vdots$$

$$\Leftrightarrow \left\langle \text{Leib from I.1} \right\rangle$$

$$A' \qquad \text{Thus, } \vdash A' \equiv A \qquad (*)$$

By soundness, we also have
$$\models_{taut} A' \equiv A$$
 (**)

So, say $\models_{taut} A$. By (**) we have $\models_{taut} A'$, and by 1.3 we obtain $\vdash A'$. By (*) and Eqn we get $\vdash A$.

Post's theorem is often called the "Completeness Theorem"[†] of Propositional Calculus. It shows that the syntactic manipulation apparatus certifies the "whole truth" (tautologyhood) in the propositional case.

[†]Which is really a *Meta*theorem, right?

1.5 Corollary. If $A_1, \ldots, A_n \models_{taut} B$, then $A_1, \ldots, A_n \vdash B$.

Proof. It is an easy semantic exercise to see that

$$\models_{taut} A_1 \to \ldots \to A_n \to B.$$

By 1.4,

$$\vdash A_1 \to \ldots \to A_n \to B$$

hence

$$A_1, \dots, A_n \vdash A_1 \to \dots \to A_n \to B$$
 (1)

Applying modus ponens n times to (1) we get

$$A_1, \ldots, A_n \vdash B$$

\$

The above corollary is very convenient.

It says that any (correct) schema $A_1, \ldots, A_n \models B$ leads to a derived rule of inference, $A_1, \ldots, A_n \vdash B$.

In particular, combining with the transitivity of ⊢ metatheorem, we get

Thus —unless otherwise requested!— we can, from now on, rigorously mix syntactic with semantic justifications of our proof steps.

For example, we have at once $A \wedge B \vdash A$, because (trivially) $A \wedge B \models_{taut} A$ (compare with our earlier, much longer, proof given in class).

2. Deduction Theorem, Proof by Contradiction

2.1 Metatheorem. (The Deduction Theorem) If $\Gamma, A \vdash B$, then $\Gamma \vdash A \rightarrow B$, where " Γ, A " means "all the assumptions in Γ , plus the assumption A" (in set notation this would be $\Gamma \cup \{A\}$).

Proof. Let $G_1, \ldots, G_n \subseteq \Gamma$ be a finite set of formulae used in a (Γ, A) -proof of B.

Thus also $G_1, \ldots, G_n, A \vdash B$.

By soundness,

$$G_1, \dots, G_n, A \models_{taut} B$$
 (1)

But then,

$$G_1, \ldots, G_n \models_{taut} A \to B$$

(Let a v make all G_i **t**. What does it do to the rhs of \models_{taut} ? If A is **f** then rhs is **t**. If not, then (1) makes B **t** and we are done.)

Thus, by 1.5,
$$G_1, \ldots, G_n \vdash A \to B$$
.

The mathematician, or indeed the mathematics practitioner, uses the Deduction theorem all the time, without stopping to think about it. Metatheorem 2.1 above makes an honest person of such a mathematician or practitioner.

The everyday "style" of applying the Metatheorem goes like this: Say we have all sorts of assumptions (nonlogical axioms) and we want, under these assumptions, to "prove" that "if A, then B" (verbose form of " $A \to B$ "). We start by **adding** A to our assumptions, often with the words, "Assume A". We then proceed and prove just B (not $A \to B$), and at that point we rest our case.

Thus, we may view an application of the Deduction theorem as a simplification of the proof-task. It allows us to "split" an implication $A \to B$ that we want to prove, moving its premise to join our other assumptions. We now have to prove a *simpler formula*, B, with the help of *stronger* assumptions (that is, all we knew so far, plus A). That often makes our task so much easier!

2.2 Definition. A set of formulas Γ is inconsistent or contradictory iff Γ proves every formula A.

An inconsistent Γ proves all formulae. For example $p \wedge \neg p$. This justifies the term "contradictory" in the definition.

2.3 Lemma. Γ *is inconsistent iff* $\Gamma \vdash \bot$.

Proof. only if-part. If Γ is as in 2.2, in particular it proves \bot .

if-part. Say, conversely, that we have $\Gamma \vdash \bot$. Then, since $\bot \vdash A$ for any A (see midterm solutions*), we get $\Gamma \vdash A$ for any A.

2.4 Metatheorem. $\Gamma \vdash A$ iff $\Gamma, \neg A$ is inconsistent.

Proof. if-part. So let (by 2.3)

$$\Gamma, \neg A \vdash \bot$$

Hence

$$\Gamma \vdash \neg A \to \bot \tag{1}$$

by the Deduction theorem. However $\neg A \rightarrow \bot \models_{taut} A$ (Why?), hence, by Corollary 1.6 and (1) above, $\Gamma \vdash A$.

only if-part. So let

$$\Gamma \vdash A$$

Then also

$$\Gamma, \neg A \vdash A$$
 (2)

Moreover, trivially,

$$\Gamma, \neg A \vdash \neg A$$
 (3)

Since $A, \neg A \models_{taut} \bot$, (2) and (3) yield $\Gamma, \neg A \vdash \bot$ via Corollary 1.6, and we are done by 2.3.

^{*}Or use 1.5 and the trivial fact that $\bot \models_{taut} A$ for any A.

 $\stackrel{\textstyle >}{\simeq}$ 2.4 legitimizes the tool of "proof by contradiction" that goes all the way back to the ancient Greek mathematicians: To prove A assume instead the opposite $(\neg A)$. Proceed then to obtain a contradiction. This being accomplished, it is as good as having proved A.
